

Assignment

Create a movie library web application with the below features using any tech stack of your choice -

1. The application must have user authentication (Sign In/ Sign Up)
2. After logging in users will be navigated to the home screen where they should see a search option where they can search movies and see details of those movies.
3. They can create a list of movies by adding the movies to lists. (Similar to youtube playlists). On the home page, different movie lists created by that user will be displayed.
4. These lists can be either public (anyone with a link to the list can see this) or private (only the person who created can see this list)
5. You can use [OMDB API](#) for the movie search option.
6. The Search & List page should have a nice layout, taking inspiration from other websites/applications.
7. Include Steps to run (Readme file) in the project as well.
8. You must host their projects online and provide working links of the application as well as code. (e.g. Netlify, Vercel, Heroku, JSBin etc.)
